

INTELLECTUAL PROPERTY RIGHTS IN THE GLOBAL ECONOMY

CHAPTER THREE

THE ECONOMICS OF INTELLECTUAL PROPERTY RIGHTS AND GLOBALIZATION: DANCING THE DUAL DISTORTION

Keith E. Maskus
Department of Economics, University of Colorado at Boulder

Final draft

Human thought is astonishingly creative in finding solutions to applied technical and scientific problems, in communicating the existence and quality of products and persuading consumers to buy them, and in expressing images and thoughts. These intellectual efforts create new technologies, describe new ways of doing things, develop new products and services, and expand the cultural richness of society. They result in intellectual assets, or pieces of information, that may have economic value if put into use in the marketplace. Such assets are called intellectual property to the extent they bear recognized ownership. The economic returns to creating them depend on their costs of creation, their desirability to potential users, the structure of markets in which they are sold, and the legal rights established to permit property owners to control their use. The legal devices that provide such control are called intellectual property rights.

In broad terms, three distinct philosophies about the nature of intellectual property and its protection may be discerned from history. First, the *natural-rights view*, stemming from some European traditions, assigns ownership of mental creations to their inventors and artists under the precept that failure to do so constitutes theft of the fruits of their effort and inspiration. Moreover, creators should be awarded rights to control any reworking of their ideas and expressions. The moral view of IPRs exists largely independently of any thoughts about the incentive effects or economic costs and benefits of regulation. This approach remains in evidence today in strong protection for artists' moral rights in European law.

In contrast, under what might be called the *public-rights view*, it is inappropriate to assign private property rights in intellectual creations. Rather, information belongs in the public domain because free access to information is central to social cohesion and learning. This approach found its strongest application in socialist systems, which did not recognize

the notion of private ownership of intellectual assets. The task of generating knowledge fell to the state and the fruits of its invention were provided widely to potential users, at least in principle. This precept still underlies many conceptions of the nature of information in several developing countries.

There is much room between these extreme positions for recognizing that IPRs may be assigned and regulated for purposes of social and economic policy. Most legal systems adopt a *utilitarian view*, in which IPRs are designed to strike a balance between needs for invention and creation, on the one hand, and needs for diffusion and access, on the other. Private property rights in information bear both benefits and costs, suggesting that they may be designed with incentives and tradeoffs in mind. This is the point of departure taken by economic analysis of IPRs.

3.1. Economics of Intellectual Property Rights

Designing an effective and appropriate system of IPRs is complex for any country. The mechanisms by which IPRs operate vary across functional areas (patents, trademarks, copyrights, *sui generis* forms of protection, and rules against disclosure of trade secrets) and their importance differs across sectors. Indeed, as discussed below, the nature and purposes of these mechanisms are distinctive although they share certain fundamental characteristics bringing them under the IPRs umbrella. The strength of IPRs depends on demand characteristics, market structure, and other forms of business and competition regulation. However, the essential economic processes may be described in simple terms.

3.1a. Static and Dynamic Failures in Markets for Information

Because intellectual property is based on information, it bears traits of a public good in two separate but important ways. First, it is *non-rival* because one person's use of it does not diminish another's use. Consider a new means of production, a composition of music, a brand name, or a computer program, all of which may be used or enjoyed by multiple individuals. In this context, it is optimal in a static sense to permit wide access to use of intellectual property. Indeed, the public interest is rather extreme in that the marginal cost of providing another blueprint, diskette, or videotape to an additional user may be low or zero. Unlike the case of physical property, a multiplicity of users does not raise congestion costs in the exploitation of intellectual property.

The second characteristic is that intellectual property may be *non-excludable* through private means. That is, it may not be possible to prevent others from using the information without authorization. If an intellectual effort is potentially valuable but easily copied or used by others, there will be free riding by second comers. In turn, there may be no incentive to incur the costs of creating it. Society has a dynamic interest in avoiding this outcome by providing defined property rights in information. In some cases private mechanisms, such as market lead times, difficulty in copying or imitating particular technologies, and marketing strategies, provide natural incentives to create and exploit information. Accordingly, the strength of this dynamic argument for protection depends on circumstances of market structure and technological complexity.

The fundamental tradeoff in setting IPRs is inescapable. On the one hand, static efficiency requires providing wide access to users at marginal social cost, which may be quite low. On the other hand, dynamic efficiency requires ensuring incentives to invest in new information for which social value exceeds development costs. These are both

legitimate public goals and there is a clear conflict between them. Economists often state this problem by noting that IPRs operate on the mixture of these two market distortions.

Excessively weak property rights satisfy the static goal but suffer the dynamic distortion of insufficient incentives to create intellectual property. The economy suffers slower growth, more limited culture, and lower product quality. Excessively strong IPRs favor the dynamic goal but generate the static distortion of insufficient access. The economy suffers from inadequate dissemination of new information. A frequently used alternative expression of this tradeoff is that IPRs generate monopoly positions that reduce current consumer welfare in return for providing adequate payoffs to innovation, which then raises future consumer welfare.¹

The basic tradeoff is simply illustrated in Figure 3.1, which demonstrates a linear demand and marginal revenue for a product that has been invented and may be supplied to the market at constant marginal cost. Once the product is available, ex-post optimality requires that it sell for marginal cost at point C, generating consumer benefits in the area $AP_C C$. However, the solution at C, which would emerge in a competitive market in which all firms could costlessly imitate the product and sell a close substitute, generates no rents with which to cover costs of the original research and development program. Therefore, ex-ante there would be no such investment, the product would go undeveloped, and the entire consumer benefit area would disappear.

An alternative solution is to create a monopoly in the good through an intellectual property right, such as a patent. In this case the firm would offer the product at point M,

¹ This description is most apt for patents, which support exclusivity over the use of an idea. Patents are the subject of the overwhelming majority of theoretical studies by economists. It is somewhat less appropriate for copyrights, which generate ownership of a particular expression, and trademarks, which protect the use of a distinctive mark or symbol.

earning monopoly rents of area $P_M P_C B M$. These rents, which represent a transfer from consumers to inventors ex-post, are the return to the original investment in product development. The economy suffers a deadweight loss of area $M B C$ in comparison with the competitive (but unattainable) solution at point C . Compared to having no innovation, however, society achieves a net gain of remaining consumer surplus plus monopoly profits, less associated R&D costs.

Figure 3.1 about here

This simple theory shows the need for public intervention to stimulate invention in cases where ex-post competition would reduce market price to the competitive level and deter the ex-ante costly investment. In principle, society would provide support that is just sufficient to induce the introduction of all innovations for which optimal ex-post consumer surplus exceeds R&D costs. Intellectual property rights are incapable of operating so precisely and are, therefore, second-best remedies for the underlying market distortions. Accordingly, protection might be too weak, resulting in foregone innovation, or too strong, generating surplus transfers to inventors and sacrificing available benefits from consumer access. Note also that a poorly struck bargain could slow down economic growth to the extent that access to protected technologies is required to induce incremental innovations and artistic creation, which is how the bulk of innovation occurs.

Within this fundamental problem of dual distortions lie numerous economic issues of considerable interest and concern. First, rights to own information impose other costs on society. For example, rent-seeking for IPRs may be a serious problem because the property

right is being invented or discovered anew. There is no ownership until the creation is made. Thus, a strong IPRs system may cause wasteful duplication of investment in R&D (that is, patent races) plus costly effort to assert ownership rights. Further, technical and judicial actions to enforce rights through excluding free riders may be costly. Finally, the costs of transferring rights to information can be high if there is uncertainty about the value of the information, about monitoring its use by those who buy or license it, or if there are other contracting costs. This problem leads to serious issues of antitrust policy in determining "fair" or "efficient" means of transferring intellectual property rights. These costs should be taken into account in assessing IPRs systems.

So also should external benefits that emerge from invention. The social value of information may be greater than the private market revenues it generates, because there may be market failures in R&D programs and creation of intellectual property. For example, the social value of an invention would exceed private revenues if there were positive consumption externalities, such as network gains from computer systems, software standards, or inoculations. Similarly, there is surplus social value whenever there are cost reductions that spill over to other uses without market compensation. Examples here might include accounting systems and weather satellites. Note the implication that if such spillovers were easier under weak patents, an economy optimally could choose to provide limited protection. Risk aversion in undertaking high-cost R&D programs also could result in deficient private incentives to create the socially optimal amount of innovation, while such deficiencies would also sacrifice potential scale economies in research activities.

In essence, the main goal of an intellectual property system should be to create economic incentives that maximize the discounted present value of the difference between

the social benefits and social costs of information creation, including the costs of administering the system. The net effects of IPRs on social values versus private values are unclear. Much depends on demand parameters, the cost-reducing effects of process innovations, and market structures. Evidence suggests that there are large spillover gains from major inventions, while IPRs on smaller inventions generally do not create significant monopoly rents. Thus, there is likely a presumption in favor of strong IPRs in most societies on the grounds that private markets are inadequate to induce socially optimal information creation.

Setting an optimal policy for promoting invention and innovation requires accounting for numerous market characteristics in each product or artistic area. These characteristics include prospective demand and growth in demand, potential spillovers, R&D costs and the costs of duplicative races, potential impacts on market structure, and competitive aspects in the economy. Many of these characteristics are highly uncertain at the time decisions on providing IPRs are made, suggesting that finely tuned policies are unworkable. If it were possible to do so precisely, an economy could develop a system of IPRs that would vary in the scope and length of protection with each potential new invention or creation. Further, there would be specific limits on protection due to the costs of providing and enforcing IPRs. But this task is impossible due to uncertainty and is itself subject to severe government failure associated with poor choices and rent-seeking.

An alternative policy regime would call for the government to retain a monopoly over the development of technology and product creation, funding all development itself. It could then provide wide dissemination for use at low cost. As economists note, however, it is unlikely that governments would react efficiently to changing market preferences and

technical information. Monopolized research in the former Soviet Union and China, for example, largely failed to produce technologies and products that could be moved into commercial streams.

Between these extremes countries might pursue systems that mix incentives for private information creation through intellectual property rights with public supports of various kinds. In the United States, for example, research in the defense and aerospace industries is largely undertaken in, or funded by, public agencies. Considerable public research subventions are made to university researchers working on problems and developing applied solutions that could find their way into private markets. Governments also subsidize artistic creation, libraries, and museums.

While the issue is complex, it is fair to say that public provision of new goods and technologies through government procurement and nationalized research programs has not proven effective in stimulating and disseminating knowledge. Market-based approaches, in which governments set rules for protecting the fruits of invention but ensure competition in the creative stages, seem to be more flexible. Intellectual property rights are an obvious solution to this problem.

In setting rules governing intellectual property rights, societies must strike a balance between the needs of inventors to control exploitation of their new information and the needs of users, including consumers and potential competitors working to develop follow-on inventions and innovations. Stated another way, the system should find an appropriate balance between creating and disseminating intellectual property. If the system creates new innovations that are not put widely into use it may be less beneficial than a regime that places less emphasis on creation but assures broad dissemination of new ideas and creative

works.² To put it in different terms, many patents are never placed into commercial use because their holders do not see them as commercially viable. Thus, commercialization incentives are as important as incentives for creation and invention.

In this context, the system should allow sufficiently market-based incentives for creation, should try to minimize the costs of innovative activity, and should provide for timely disclosure of innovation or creation and reasonable fair use with economic and social goals in mind. Moreover, it is important for IPRs to interact coherently with other regulatory or economic systems, including antitrust policy, trade and FDI policies affecting the values of IPRs, and general technology development strategies. Such strategies include industrial policies, such as R&D subsidies, R&D joint ventures, and public grants to universities and agencies for basic R&D, and are influenced by how IPRs are granted and protected.

3.1b. Intellectual Property Rights in an Open Economy

The preceding description captures the essence of the argument for intellectual property rights in a closed economy. The situation is more complicated in a world of many countries that are linked by trade and investment. The first difference is evident from Figure 3.1. For a country that imports or produces an imitative product or technology at the competitive price, a decision to award protection transfers monopoly rents to foreign firms, thereby suffering a static loss of area $P_M P_C C M$, associated with the worsened terms of trade. It also reduces output by local firms that are not authorized to produce by the right-holder. If the country is too small for such a transfer to induce additional R&D by foreign firms on products that meet local demands, the impact is a straightforward loss in welfare. This

² Again, this is essentially a utilitarian statement. Different societies may place different values on creation

simple observation underlies much of the resistance to stronger IPRs that persists in many developing countries.

Technology-importing countries may prefer weak IPRs as a form of strategic trade policy. In addition to the discipline on monopoly pricing indicated in Figure 3.1, weak patents, trade secrets, trademarks, and copyrights allow uncompensated imitation and copying of foreign products and technologies. Thus, limited IPRs may provide an inexpensive means of technology transfer, to the extent that imitative and adaptive capabilities are effective. International technology spillovers through uncompensated imitation have long been considered an important justification for refusing to grant patents (Vaitsos, 1972).

Thus, countries that import goods and technologies that may be subject to IPRs coverage count several costs of protection, including higher prices for imports, potential competitive abuses in the exploitation of IPRs, employment losses in imitative and copying industries, and restricted access to international technologies.

However, greater IPRs protection in developing countries generates domestic benefits as well. One gain would be more domestic innovation, which likely would be better suited to local needs than would foreign innovation. The prospects for such innovation depend, among other things, on local market size and domestic technological capacities. Such benefits seem particularly important through the exercise of trademarks, because product development reacts elastically to such protection in developing countries (Maskus, 1997b). Further benefits stem from the fact that stronger IPRs expand incentives for trade

and inward FDI and reduce costs of writing and monitoring contracts for technology licenses.³

Intellectual property rights are national in scope, permitting considerable differences across nations in their protection regimes. International variations in IPRs have been the subject of trade conflict for a long time. For example, the first U.S. Copyright Act, adopted by the initial American congress, actively sought to encourage the development of the publishing industry by awarding rights to print, reprint, publish, and sell literary works only to domestic citizens and residents (Post, 1998). Foreigners were excluded from attaining copyrights and the law explicitly permitted parallel importation of works copyrighted abroad. In consequence, American publishers were able to publish and sell foreign literary creations cheaply, which attracted sharp criticism, especially from British authors. Throughout several revisions of the law in the 19th century, discrimination against foreign authors and publishers remained central to U.S. copyright law, as it did in many major countries. Only with the passage of the International Copyright Act of 1891 did the U.S. government recognize equal treatment for foreigners, and then only for countries offering reciprocal treatment to American authors. This change in the law arose because of both pressures from foreign governments and, more importantly, growing interests on the part of U.S. authors and publishers to receive protection abroad. Even so, the new law imposed discriminatory requirements on foreigners and remained explicitly protectionist.⁴ Only with

³ These issues are discussed at length in Chapter 4.

⁴ Despite the non-discrimination written into this law, it still imposed difficult formalities on foreign publishers, such as requirements for copyright notice, registration, and deposit of works, with which foreigners found it difficult to comply. Moreover, it added the so-called “manufacturing clause”, which mandated that any printed book or journal in the English language had to be printed from type set in the United States, and printed and bound in the United States, in order to receive copyright protection. The manufacturing clause, which was the subject of an adverse GATT ruling, remained a part of U.S. law until the revision of the Copyright Act in 1976.

American accession to the Berne Convention in 1989 did all vestiges of such discrimination in the publishing industry disappear.

The history of U.S. copyright law demonstrates convincingly that countries that are substantial net importers of products and technologies, which potentially are subject to IPRs protection, consider weak protection to be a form of infant-industry support. To the extent that the losing interests from weak protection are foreign, they command little weight in the policy framework. Rather, the creation of indigenous firms that develop and produce items that require security from piracy has been the traditional spur toward stronger IPRs in the past. It is interesting to note one important and substantive potential difference between infant-industry trade protection and IPRs, however. Trade protection tends to create inefficient industries that act as a block to future trade liberalization. To the degree that weak IPRs induce the development of innovative firms, they generate a future constituency for systemic reform.⁵ Whether weak protection of intellectual property in fact has such an impact remains open for debate, as discussed later in this volume.

The copyright story also indicates that weak IPRs are viewed as a means for achieving non-economic objectives, such as the growth or maintenance of domestic cultural industries. The most prevalent of such objectives in the global economy is the preservation of public health through limiting costs of procuring medicines, simply by virtue of not patenting them. Thus, many developed nations, including Italy and Japan, did not provide patents for pharmaceutical products until the late 1970s, while Canada only removed its compulsory licensing requirements in patented drugs in 1993.

⁵ I am grateful to Catherine Mann for this insight.

Indeed, significant controversies persist over differences in IPRs among developed countries. For example, the United States remained dissatisfied with aspects of the Japanese patent system until its recent reform, claiming that it encouraged excessive filing of narrow patent claims and discouraged patenting by foreign firms. The United States and the European Union have moved toward patenting software with demonstrated industrial utility, but they differ considerably in their rules concerning acceptable decompilation of computer programs for purposes of reverse engineering. Negotiations continue over the scope of protection for geographic indications, with the United States preferring less extensive and protective standards than the EU. Developed countries also differ markedly in their treatment of various aspects of copyrights.

In the world economy today, however, the largest differences in intellectual property protection occur along North-South lines. From the standpoint of information developers in the innovative countries of the North, there are several primary shortcomings in the regimes of many developing countries. For example, inadequate enforcement of copyrights and trademarks allows extensive copying of entertainment and software products and unauthorized use or misrepresentation of well-known trademarks. Second, pharmaceutical and chemical products have generally been excluded from patent protection. Similarly, the absence of patent protection for biotechnological inventions and patents or *sui generis* rights for plant varieties has been controversial. Another concern focuses on the practice, albeit rare, of issuing compulsory licenses with inadequate compensation to firms that are perceived to be exercising their patent insufficiently to achieve desired consumer benefits or technology transfer. Also problematic is the often weak or poorly defined system of rules protecting trade secrets.

3.2. Structures and Objectives of IPRs

Despite the terminology in the discussion surrounding Figure 3.1, it is inaccurate to think of IPRs as mechanisms for creating monopolies. Intellectual property rights define the extent to which their owners may exclude others from activities that infringe or damage the property. Thus, IPRs set out and protect the boundaries of legal means of competition among firms seeking to exploit the value of creative assets. Efforts to extend the rights beyond these boundaries are denied, in principle. In this context, it is more fruitful to conceive of IPRs as rules regulating the terms of static and dynamic competition, rather than mechanisms for creating legal monopolies. While IPRs do create market power, the impact on competition varies as widely across products, technologies, and countries as it does across the form of rights granted and the scope of protection. Indeed, the strength of the protection depends not only on the scope of the rights granted, but also on the ability of competitors to develop non-infringing products and technologies and the ability of consumers to substitute among supply sources.

This section describes the general structure of various forms of IPRs, noting the different objectives they try to fulfill and limitations placed on them in order to ensure their proper functioning.⁶ While the focus is on the economics of IPRs, rather than their legal characteristics, it is useful to introduce certain legal terms that come up throughout the volume. To aid interpretation, Table 3.1 lists each area of intellectual property and its main forms of protection.

⁶ An excellent source on this material is Besen and Raskind (1991).

3.2a. Patents

A patent provides its owner the right to exclude all others from making, selling, importing, or using the product or process named in the patent without authorization for a fixed period of time. In principle it is the most powerful instrument in the IPRs system because it provides exclusive rights to the physical representation, in the forms of goods, blueprints, formulas, and designs, of ideas with industrial applicability. Because they protect technologies and products to which follower countries wish to have access, they are also among the most controversial forms of intellectual property rights.⁷ This is particularly true in key sectors where the public interest may call for wide dissemination at moderate prices.

Legal and Economic Principles

Patents may be awarded in any area of technology to any new and useful process, product, composition of matter, and, in the United States, ornamental designs for products. However, some subject matter may be excluded from patentability for purposes of preserving morality, national security, and public health. In most systems patents also are not awarded for fundamental scientific discoveries flowing from the basic physical laws of nature, including mathematical algorithms. Under the nearly universal “first-to-file” rule, patents are granted to applicants who first submit the appropriate documents. The United States is an exception, awarding patents to inventors who can document that they were the first to invent the product or technology under a “first-to-invent” rule.⁸

For an invention to be patentable it must meet three criteria: it must be novel (that is, previously unknown), it must contain an inventive step (that is, a step that is non-obvious to

⁷ A similar statement applies to copyrights for software and electronic databases.

one skilled in the area of technology it represents), and it must be useful or have industrial applicability. Novelty and non-obviousness are important aspects of this set, for they set the technical bar that patent examiners must certify has been met in order to award protection.

In general there are three types of patents for which an inventor may apply, though not all countries recognize all three forms. First, *invention patents* (or simply patents) require a significant degree of non-obviousness, meaning that they embody discrete advances in technology. They receive the longest term of protection, with the global standard being twenty years under the TRIPS Agreement. Second, *utility models* are awarded to mechanical inventions with less stringent non-obviousness standards. These inventions, which tend to be incremental improvements in existing products and technologies, embody less technological progress and receive protection of shorter duration. Third, *industrial designs* protect the aesthetic or ornamental aspects, such as shape, pattern, or color, of a useful commercial article. The design must be associated with the industrial article itself. Designs are protected from unauthorized copying or imitation for a prescribed period, with a minimum period of ten years required by TRIPS.

Table 3.1 about here

Though patents are provided for a fixed length of time, the breadth or scope of the patent may vary. Inventors make claims about the protectable novelty of their inventions but examiners may narrow the claim or reject it. Patent breadth is provided as a technical matter; examiners do not try to consider economic efficiency in patent grants. While the

⁸ The United States was preparing legislation in 1999 to move toward the first-to-file system, consistent

claims recognized in a patent grant establish the literal terms of protected subject matter, patent scope may be complemented by a legal “doctrine of equivalents”. This doctrine permits patent owners to litigate against competing products and technologies that may be shown to rely on techniques that are essentially equivalent to those in the patent grant. The scope of this doctrine may be narrow or broad, depending on national legislation.

In economic terms, whether a patent should cover narrow claims over a long life or broad claims for a short time depends on expected market competition and the likelihood of spillover effects (Klemperer, 1990). These considerations argue for structuring patents to meet specific conditions of each application, which is impractical in legal terms. Some economists mention also the height of patent protection, which refers to the power of a particular grant to permit its recipient to limit or control development of follow-on technologies.

Four arguments may be put forward to justify the award of market power through patent grants.⁹ First, patents provide an incentive to undertake the research effort and costs required to invent new technologies and products and bring them to market. Thus, patents are a primary solution to the appropriability problem, discussed earlier, in the area of industrial invention and innovation. Note that the incentives must be sufficient not only to induce invention but also to encourage commercialization. A patent that is not “worked” through production or sales, even if it were commercially viable to do so, locks up an area of technology in return for little gain to consumers. In consequence, some countries include working requirements, within particular time periods, for patent grants to be sustained.¹⁰ An

with stipulations in the TRIPS Agreement.

⁹ Mazzoleni and Nelson (1996) provide a trenchant analysis.

¹⁰ Note that domestic production requirements may be effectively equivalent to a trade restraint or an investment mandate, pointing out the intricate interplay between IPRs and commercial policy.

important variant of the commercialization-inducement theory of patents is that patents may reduce transaction costs involved in licensing, resulting in broader sharing of new information.

A second argument is that patents serve to expand the public stock of technical knowledge. It has long been recognized that in return for creating market exclusivity through a patent, society requires some compensation. For this reason, patents bear a disclosure requirement, in which the technical aspects of patents are made known and others are free to use the information to develop new inventions that do not violate the patent claim. Note that the narrower the claim, the easier it is to invent around the patent. Similarly, the sooner the patent application is laid open for inspection by the public, the more rapidly the technical information it contains becomes known. In this sense, patents may be structured to be dynamically pro-competitive even if they are statically anti-competitive. Indeed, advocates of strong patent rights believe that they create significant competition with long-run consumer benefits.

A third justification is that the awarding of market power through patent grants may facilitate the establishment of markets for developing and disseminating knowledge.¹¹ Absent exclusive rights to new information, these markets themselves might fail to develop, an observation that is consistent with the practical situation in some developing countries, as discussed later in the volume.

A final argument is that well-recognized patent claims encourage the orderly development of follow-on innovation, much like prospecting claims for mineral deposits.¹² In this view, ownership of a broad patent on an initial invention supports fruitful

¹¹ See David (1993).

development of related innovation by the owner or its licensees. Without such rights, there may be wasteful duplication of R&D targeted on applications of the controlling technology. This justification for awarding monopoly rights on a technology that permits control of subsequent exploratory research is controversial, even within leading technological nations such as the United States.

It is evident that the market power associated with patents may impose social costs even as it encourages invention and commercialization. Accordingly, societies place limits on the power of patent grants. As already noted, patents are limited in duration and breadth of the claims awarded. They carry disclosure requirements and, in many nations, must be worked in order to sustain protection. These limitations vary across countries and, as will be discussed in later chapters, may be selected to affect the competitive conditions associated with the patent regime. Moreover, the potential for abusing the market power inherent in patent grants is recognized in national competition policies. Attempts to extend protection beyond the patent grant are considered anticompetitive and may be subject to antimonopoly remedies, including orders to cease the practice, compulsory licenses to competing firms of key products or technologies, and even revocation of patents. Some examples of potential abuses include horizontal restraints on trade associated with patent licensing, tied sales that extend the patent to an unpatented product, exclusive grant-back conditions in technology contracts, and conditions preventing challenges to patent validity. This issue is taken up further in Chapter 7.

The Effectiveness of Patents

¹² The “prospect theory” of patents is associated with Kitch (1977).

Many observers question the need for strong patent systems in achieving their stated goals. An obvious question is whether patents are necessary to stimulate investment in invention and commercialization. Competitive rivalry in technology development may spur invention naturally. Further, market and technical barriers to imitation may allow inventive firms to charge a price above current production costs for a sufficiently long period to recover investment costs and compensate for risks taken. Scherer (1980) notes some conditions under which this situation might prevail, including imitation lags due to secrecy, imperfect information transfer, and the complexity of successful imitation. There may also be advantages in being first to market a new product through establishing a reputation for quality.

Thus, the private ability of firms to appropriate the economic returns to invention and innovation depends on several characteristics. Among these are the degree of market imperfection, the technical ease of imitation, the pace of information diffusion and firms' abilities to control it, and market demand parameters. In cases where innovation and development would happen without patent protection, its provision is redundant and potentially costly. In practice, however, it is difficult to identify such cases since inventors generally do file for patents. It may not be possible to determine whether the promise of a patent was the required stimulus to invention or its registration is an *ex-post* means of establishing claims to an invention that would have emerged anyway.

There is suggestive evidence on some of these questions. In the United States, information about new products and processes becomes available to a firm's competitors (including foreign competitors) fairly rapidly, generally in a one-to-two year period (Mansfield, 1985). The information is transferred through shifts of personnel, technical

meetings, communications with suppliers and customers, reverse engineering, and the study of patent applications. Thus, the ability of firms to retain technological advantages in-house without protection is limited.

However, the competitor's step from learning the information to imitating the new product or process may be difficult. Imitation takes time and requires investment costs, including R&D, marketing, investment in production facilities and start-up costs, and, if necessary, the need to invent around the original patent. In the United States, these costs appear to be substantial in many industries. In a sample of firms in four industries, average imitation costs totaled some 65 percent of innovation costs and imitation time equaled about 70 percent of innovation time (Mansfield, et al, 1981). These costs depended significantly on market structure. Further, except in the drugs industry, patents had small impacts on imitation costs and patented innovations were relatively easily imitated, generally within four years of initial introduction.

Mansfield (1986) sampled 100 firms in 12 U.S. manufacturing industries regarding their views of whether patents are important in making their decisions about investment in innovation. His results suggested that only in the pharmaceutical and chemical industries were patents considered essential, in the sense that more than 30 percent of their inventions would not have been developed in the absence of potential protection. In these sectors, fixed costs of R&D are high and imitation is fairly easy. In three industries (petroleum, machinery, and fabricated metal products) patents were seen as important in the development of between 10 and 20 percent of inventions, while in the other seven industries

patents were viewed as unimportant or only marginally significant in inducing R&D. These results are consistent with those reported in Levin, et al (1987).¹³

That patents may not be viewed widely as important incentives for invention in U.S. industry does not mean that firms decline to patent. In Mansfield's sample a high percentage of patentable inventions were patented, ranging from 50 percent in the primary metals sector to 86 percent in the petroleum and machinery industries. The remaining inventions were protected, to the extent possible, with trade secrets and private actions. Thus, the benefits of patent protection were seen as worth incurring the costs of patenting.

This survey evidence suggests that the elasticity of invention with respect to patents is rather small, except in certain industries. However, these surveys are rather dated. New technologies have emerged that find patent protection important, including biotechnology and plant genetics. Moreover, inventor attitudes toward the importance of patents are surely endogenous to the strength of the system. At the international level, the general weakness of the global patent system and the ease of technological spillovers could have contributed to the view of patents as unimportant (Mansfield, 1988). If so, stronger protection could alter this view and potentially raise inventive activity and economic growth. Further, there may be dynamic linkages or spillovers between product generations that would be enhanced by stronger patent regimes, causing firms to view patents as more significant over time.

A second question is whether patents are the least-cost means of stimulating invention. Patents may be a crude means of compensating inventors, resulting in inadequate returns if protection is weak or excessive returns if protection is so strong as to transfer, to inventors, revenues above costs of investment. This latter outcome often happens, at times

¹³ Taylor and Silbertson (1973) present similar evidence for the United Kingdom.

spectacularly (Scherer, 1980). It is evident that the fixed-term patent structure is ill designed to effect an optimal dynamic resource allocation. Cheung (1986) has noted that it is possible in principle to design lump-sum transfers from consumers to inventors that could stimulate the same investments in innovation without suffering the price distortions of patent grants. This argument is a variant of the case for using tax-cum-subsidy schemes over tariffs and quotas to promote certain social objectives. From a practical standpoint it suffers the same shortcomings, including the difficulty of making such transfers efficiently and political resistance to cash transfers. Further, it would be practically impossible to compute the required surplus transfer *ex ante*, given the uncertain nature of technology development. As noted earlier, the third alternative of government provision of R&D is also unwieldy and ineffective. Thus, for all its imperfections the patent system is likely the most efficient system for incenting inventive efforts, though this hypothesis essentially cannot be tested.

There is little systematic evidence that patent disclosure requirements enhance the dissemination of technical information, though Mansfield mentions the importance of this channel in his 1986 survey. The more significant factor is that the patent system may provide the necessary incentive for firms to undertake the risky, long-term R&D that leads to major technological breakthroughs, such as copying technologies, computers, and semiconductors (Scherer 1980). Around these inventions grow whole industries that use their technologies, improve on them, or develop residual applications. The social gains to large technological advances can far exceed private returns because their associated spillover benefits have a substantial positive impact on growth, a point on which there is virtually no doubt (Bresnahan, 1986). While there is little empirical evidence on the role of patents in

this process, largely due to the difficulty of constructing the appropriate counterfactual cases to study, practitioners suggest that patent protection plays an important role.

3.2b. Copyrights

Copyrights protect the rights of creators of literary and artistic works to communicate, display, or perform those works in some medium, plus the rights to make and sell copies. Copyright laws protect the expression of an idea -- its arrangement and presentation in words, musical notes, dance steps, colors, and so on -- rather than the idea itself. By tradition, literary and artistic ideas are without industrial applicability, which renders them different from patentable inventions, though this distinction has been blurred by recent technological developments as will be discussed later. Thus, the idea to render a painting of a mountain cannot be protected from others who also wish to paint it. But the particular rendition by one artist is protected from being copied, either literally or so closely as to constitute “slavish copying”.

To receive a copyright, the item must be a demonstrably original work but there is no need for novelty in the underlying idea. The particular expression must be fixed in some medium, such as a book, recording, electronic broadcast, software, or even electronic mail. It is generally not necessary to undergo registration formalities to receive a copyright because any original expression is protectable upon creation regardless of its inherent quality. Rather, it is sufficient to establish the date on which the work was created. Formal registration may be of material assistance in defending the copyright, however.

Copyrighted works are protected from unauthorized copying for long periods, typically lifetime of the creator plus 50-70 years, or 50 years in the case of corporate

copyrights. The longer period compensates for the lower degree of monopoly power accorded by copyrights than by patents. Copyrights cannot be renewed and upon their expiry the works enter the public domain into free use.

A copyright confers the rights to prevent unauthorized duplication, performance, recording, broadcast, translation, and adaptation of a work. Further, the Berne Convention requires member countries to provide “moral rights” or “authors’ rights”, by which the creator may prevent any prejudicial modification of her work even after she has sold its economic rights. Further, most countries provide “neighboring rights”, which protect the rights of those who disseminate an author’s work, such as performers, phonogram producers, and broadcasters, to prevent unauthorized duplication of their efforts. Copyright laws also typically extend rights of authors to control the development and use of derivative products, such as the fixation of literary characters on clothing.

The main exceptions to copyright protection come under the “fair use doctrine”, the terms of which vary across countries. Under this doctrine, countries define activities that are permitted to make use of protected works in the interests of educational, scientific, and technical advance. Thus, uncompensated quotation of a work is allowed, subject to appropriate citation, as is the making of limited copies for educational and research purposes. More controversial is the treatment of decompilation of computer programs for purposes of developing competing applications. In the United States, for example, many software developers consider this form of reverse engineering to be free riding that injures their original investments in program development.

The fundamental objectives of copyrights in literary and artistic property are akin to those in patents for industrial property. Creative works provide social, cultural, and

economic benefits that society wishes to secure. These works involve investment costs, including training, time, materials, technology acquisition, and the like. Moreover, marketing copyrighted products requires costly investment that is more readily recouped under the greater certainty provided by protection. If other members of society were allowed to free ride on the works without compensating their creators, the incentives to create would be severely dampened. Static economic efficiency might be achieved at the cost of lower growth in cultural identity and reduced investment in “industrially useful” expression such as software. At the same time, providing exclusive rights limits the dissemination of literary works and raises static costs of education, research, and entertainment. The copyright system reflects a compromise between these difficulties, attempting to balance the needs of creators with society’s interests in wide access to the results of their efforts.

There may be some natural market mechanisms that would provide adequate remuneration to creators in the absence of copyrights. Examples include subject matter that is relatively inaccessible, the advantages of being first in marketing the creative product, embedded devices that defeat copying of electronic products, and demand characteristics. However, most cultural creations are not naturally protected because second comers may appropriate their value through low-cost duplication and distribution activities, with little or no investment required in mastering the underlying creative effort. Indeed, free-riding competitors would focus their efforts on those creations that had proved successful in the marketplace, absolving them of any uncertainty costs and allowing them to take advantage of the marketing efforts of creators. In turn, the returns to original developers would be significantly reduced.

Rapid and dramatic improvements in copying technologies, which have emerged in recent decades, underlie growing demands for stronger global protection and extension of protection to subject areas such as software, internet transmissions, and broadcasts. These issues are complex and subtle. For example, the required technologies for receiving a satellite broadcast have evolved and become sufficiently inexpensive that it is difficult and costly for the broadcaster to practice exclusion. Some who receive the broadcast without authorization may then benefit commercially from it by displaying it to paying patrons or by re-transmitting it over local cable systems. Such actions reduce the value of the copyright owned by the program's producer and the neighboring right owned by its broadcaster, resulting in lower appropriability. The private solution, in which broadcasters scramble their signals and make them unintelligible to all but authorized receptors, may be socially inefficient. It achieves exclusion, thereby sacrificing consumer benefits, but incurs a cost to the broadcaster (or its consumers) that may approximate the original loss in copyright value, leaving a net potential loss. The United States has effected a compromise solution, in which broadcasters get limited copyright protection plus remuneration from cable operators at a price set by the government. Cable operators effectively receive a compulsory license to carry the broadcast. This solution may also be sub-optimal because compulsory licenses imply involuntary transactions by the broadcaster that may stifle further program development.

Related questions surface with respect to electronic transmission of databases and other proprietary information among computers. Again, exclusion is feasible but costly, particularly when transmission is over telecommunications networks with multiple users. Databases may be copyrighted in some nations to encourage their development and sale,

while laws covering trade secrets may help protect proprietary information. However, when such information is transmitted the difficulty of excluding unauthorized users raises policy concerns like those in broadcasts. There is a substantive international component to this issue since such transmissions are often trans-border and countries assert the right to regulate the amount and type of information flows crossing their borders.

Information technologies are particularly vulnerable to low-cost and massive copying, raising thorny issues about copyright and fair use, as will be discussed later in the volume. These are critical issues on the global IPRs agenda.

3.2c. Trademarks and Geographic Indications

Trademarks, and *service marks* protect rights to use a particular distinctive mark or name for identifying a product, service, or company name. Such marks are of material value in distributing goods and services. Because the pool of potential trademarks is limitless, they typically require only registration formalities, with an opportunity for others to protest the award of a trademark if it can be shown to infringe a prior mark. Trademarks typically may be renewed indefinitely upon periodic re-registration. Related rights include *geographic indications*, which certify that a consumer product (wines, spirits, and foodstuffs) was made in a particular place and that it embodies physical characteristics of that location, such as soil conditions and climate, or that it meets quality conditions implicit in the reputation of a location. Though there is some variation in how these mechanisms operate and their impacts on economic incentives, they all have the same basic purposes, which are to lower consumers' search costs, protect consumers from fraud regarding the origin of a product, and safeguard commercial reputations for quality.

Like patents and copyrights, trademarks carry legal authority to enforce the exclusive use of an asset created by human thought. In this case the asset is a symbol or other identifier that conveys information to the consumer about the product. If consumers view the mark as a reliable indicator of some desirable product characteristics, they would be willing to pay a premium for the good. This premium compensates the firm for the cost of developing and advertising the trademark. If competitors were allowed to duplicate the mark or use a confusingly similar mark these costs might not be recoverable.

The distinctiveness of trademarks is important, for protecting non-distinctive marks could impose confusion and litigation costs on society without generating lower consumer search costs. Similarly, generic names, such as “car” or “microwave oven”, are not eligible for protection. In most countries outside the United States trademarks are awarded to the first person to register them. This system provides legal certainty about ownership and helps avoid inadvertent duplication of trademarks but may encourage excessive investment in monopolizing trademark development as firms attempt to register all potentially interesting or descriptive names and symbols in a prospective product line.¹⁴

In other countries it is simply first commercial use that procures a trademark and registration serves to buttress claims to first use. The advantage of this system is that trademarks provide little social benefit except when they are actually used to identify a good being sold. Its main difficulties are ambiguity about where the trademark may have been used first and the geographic extent of protection, along with an inability to avoid inadvertent duplication.

¹⁴ Landes and Posner (1987) suggest that this has been a problem in Japan, while stories about speculative or fraudulent registration are common in many countries. A modern variant of this issue is the practice of registering domain names on the internet that are quite similar to the names or trademarks of familiar enterprises.

Unlike patents and copyrights, trademarks do not protect the creation of additional knowledge, but rather the identification of the origin of a product. Critics claim that this substantive difference renders trademarks less socially valuable, in that they sustain market power without providing dynamic incentives to create new products.

A balanced view recognizes that trademarks have several positive impacts that offset the market power they might generate.¹⁵ Because trademarks indicate the inherent quality or other distinguishing features of identified products, the consumer's costs of searching for her preferred quality characteristics are lowered. This provides firms an incentive to maintain or improve quality over time in order not to erode the value of their marks. Thus, trademark protection may be expected both to raise the average quality of products on the market and to generate further product differentiation. Moreover, trademarks provide an inducement for new firms with distinctive products to enter markets, a process that can be of considerable importance for growth and market deepening in developing economies.¹⁶ Trademark protection establishes incentives for orderly distribution arrangements, which can be important in securing economies of scale. Finally, trademarks provide an outlet for consumers who desire exclusivity in their consumption. The need to protect high-end consumer trademarks, such as Chanel and Calvin Klein, is evident, since otherwise free riders would duplicate such marks and attach them to goods of lower quality and lower cost. Indeed, such well-known trademarks are the targets of most product counterfeiting in international markets.

Potential monopoly costs and consumer damages from trademarks are limited for several reasons. First, the market power associated with a particular trademark is likely to be

¹⁵ See Landes and Posner (1987) and Besen and Raskind (1991) for discussion.

small because the potential supply of competing trademarks is virtually unlimited. There are exceptions to this observation in cases where a highly successful brand in a sector with substantial fixed investment costs serves to augment entry barriers. Second, legal structures covering unfair competition generally prevent fraudulent passing off of goods and services and false and misleading advertising. Third, consumers are capable of assigning quality variations to goods. If the claimed quality is consistently not forthcoming, consumers will discount the trademark. Because firms have strong incentives to safeguard their reputations and trademarks, misleading activity should be minimal in well-functioning markets that are complemented by adequate legal systems.

Trademark infringement constitutes unauthorized duplication of a mark or use of a confusingly similar name or mark. The primary international area of contention is production, sale, and importation of counterfeit goods, which are represented as legitimate goods without authorization of the trademark holder. Counterfeiting may enhance consumer welfare by providing lower-cost alternatives but it also reduces welfare by increasing confusion, raising search costs, diminishing the value of trademarks, and lowering incentives to maintain product quality and develop new products. The fraudulent sale of low-quality food items and medicines could endanger human safety. The enforcement of rights usually is established through private litigation and it is up to the courts to determine the likelihood of confusion, whether infringement was deliberate, and what damages to assess.

3.2d. Trade Secrets

¹⁶ Maskus (1997b) discusses the importance of this process in Lebanon, while Maskus, Dougherty, and Mertha (1998) describe its operation in China.

Trade secrets are proprietary information about production processes, including such mundane, but commercially valuable, items as customer lists and organizational methods. A trade secret is protected by standard liability laws against unauthorized disclosure through commercially unfair means. These laws are torts, not IPRs in the classic sense, and do not fit well into the standard intellectual property framework. In particular, there exists no exclusive right to use the information if it leaks out fairly, in which case it enters the public domain. Trade secrets cannot be protected against learning by fair means, such as independent creation, reverse engineering, or reading public documents. Thus, a trade secret has no statutory time limit but can run out in the regular course of competition.

The traditional view of trade secrets by economists was to doubt that they could provide net economic benefits. If no disclosure is required, but market power is created, by protecting trade secrets, society must lose. But this view has changed with the growing recognition that trade secret protection may efficiently fill gaps that are created by the patent system and also provides important incentives for innovation (Reichman, 1994). There are three such gaps. First, an inventor might judge his creation to be unpatentable in legal terms but hard to imitate. Second, a firm could prefer not to disclose its process, as a patent requires, because disclosure could reduce expected profits. Third, a firm might wish to avoid the costs of patent filing.

Society could achieve economic gains from protecting trade secrets in comparison with patents. Trade-secrets laws could generate innovation, especially of the smaller, incremental kind that would have value for a limited time. Trade secrets could reduce incentives for R&D races because no patent might be awarded or sought. More reverse engineering to learn trade secrets would occur than under patent protection since the

follower firm may use its results without liability. Indeed, this could be a cheaper route for competitors to learn new technologies than reading patent applications and inventing around patent grants.

There is an interesting reason, in principle, that trade secrets law involves no liability for lawful copying. Firms are at times likely to be creators, and at other times to be copiers, of trade secrets. All have a joint interest in being able to reverse engineer each other's products in order to learn the underlying processes. Legal protection against reverse engineering would impose high costs on the system that, in expected value terms, could be higher for every firm than the expected costs of imposing limited trade secrets protection.¹⁷

Trade secrets law is dichotomous. Full liability pertains when there is an illegal attempt to learn a proprietary process. No liability incurs when the attempt is legal. This structure acts as an incentive to firms to engage in legitimate learning activities, which in turn could stimulate greater dynamic competition. The task for policymakers in each country is to define the boundaries of legal attempts to learn a rival firm's trade secrets.

3.2e. Hybrid Forms of Intellectual Property Protection

Recent advances in technology have strained the classical categories of intellectual property described above because new forms of creative activity do not easily fit into them.¹⁸ For example, computer software embodies elements of both literary expression, in the form of its binary code, and industrial utility to the extent that programs are integral to production processes. In the former case, protection via copyrights is indicated, which is largely the

¹⁷ This claim was articulated most forcefully by Reichman (1994, 1999). See also Besen and Raskind (1991) and Landes and Posner (1987).

¹⁸ Some of these issues are explored further in the next section.

global standard. However, programs of industrial utility that meet novelty and non-obviousness requirements are patentable in many systems, including the United States, the EU, and Japan. Questions also surface over the extent to which decompilation of programs should be permitted in order to develop competing applications and maintain interoperability of software.¹⁹

Similar comments apply to aspects of semiconductor topography, or chip design. Such designs do not seem to be literary expressions, yet it is relatively straightforward to copy them. At the same time, patent protection of layout designs seems excessive since the designs themselves may not meet novelty requirements. Accordingly, chip topographies have attracted their own form of *sui generis* protection that requires only originality (as in copyrights) but provides ten years of exclusive rights in production, sales, and imports.

An additional form of protection is plant breeders' rights (PBRs), which permit developers of new plant varieties to control their marketing and use. These rights operate much like patents, being provided for fixed terms. However, rather than requirements that new plants be non-obvious and have industrial utility, a weaker stipulation exists that plants be distinctive from earlier varieties and genetically stable. They are controversial in developing economies with significant farming sectors but little capacity in the private sector for innovation in agriculture and horticulture.

Finally, questions persist about whether copyright protection is adequate to encourage electronic transmission of broadcasts, internet materials, and databases (Reichman and Samuelson, 1997). While copyrights have emerged as the global standard in these areas, additional mechanisms may be required to discipline unauthorized copying and commercial

¹⁹ Samuelson, et al (1994) advocate *sui generis* protection for software, but their proposal has not yet been

use of materials transmitted electronically. Further discussion on this point is provided below.

3.3. Sectoral Reliance on IPRs

Just as IPRs vary considerably along functional grounds, their importance differs greatly among economic sectors. In order to understand the sources of pressure for change in global protection it is useful to discuss the dependence of critical sectors on various forms of intellectual property rights. This discussion should not obscure the fact that all sectors make extensive use of IPRs. Patents are important in machinery, equipment, and motor vehicles, for example, and virtually all goods and services are marketed with trademarks. Copyrights protect publishers of magazines, industrial manuals, and blueprints. Moreover, intellectual property rights of various forms interact in a portfolio of protection for firms. To illustrate, characters developed by the Walt Disney company may be copyrighted in films, books, and derivative products, but they are equally protected by the Disney trademarks.

3.3a. The “Patents Complex” of Pharmaceuticals, Biotechnology, and Plant Varieties

Patents are awarded in all fields of technology and are sought by innovative firms in all industrial sectors. However, the promise of patent protection is seen as particularly critical for capturing returns to basic invention in pharmaceuticals, agricultural and industrial chemicals, and biotechnology. These industries embody high costs of research and product development but face considerable appropriability problems. It is not difficult for competitors to determine the molecular composition of pharmaceutical compounds or the

genetic makeup of biotechnological inventions, and to develop imitative products. Such inventions wear secrets “on their face” in the terminology of Reichman (1994). Accordingly, drug manufacturers and biotechnology firms in the United States and Europe are in the forefront of programs to strengthen global patent protection. The situation is similar for new plant varieties, which typically entail substantial innovation costs that may not be recoverable if exclusionary limits are not placed on the ability to duplicate and resell seeds.

At the same time, drugs, genetic inventions, and seed varieties are precisely the technologies that attract greatest controversy in the IPRs arena. There is widespread concern in developing countries over potential for monopoly pricing and limited distribution of new technologies and products in response to stronger patents. I address these concerns in a later chapter. At this point it is useful to discuss briefly the economics of each of these sectors in order to demonstrate the importance of patents. Note that these three lines of business are closely related. Research and production activities are often conducted in all of them by particular chemical, pharmaceutical, and agribusiness companies. Biotechnological inventions are themselves sources of new medicines, industrial processes, and food products.

Pharmaceuticals

The global pharmaceutical industry is both hierarchical and intensely competitive. At the top level lie a relatively small number of large multinational enterprises, headquartered in the United States, Switzerland, Germany, the United Kingdom, and Japan, that undertake virtually all the basic pharmaceutical research done within private entities. A wave of mergers in the 1990s has increased concentration at this level of the industry. These

enterprises are truly global in scope. For example, the American pharmaceutical industry has far more foreign production and distribution facilities per parent enterprise than any other U.S. manufacturing sector (Maskus, 1998b). In large part this internationalization reflects cost savings from transporting bulk ingredients, with assembly into dosages and distribution undertaken locally. It also reflects the significant price advantages that trademark recognition affords in the industry, even in countries with weak patent laws, such as India (Lanjouw, 1997).

Patented pharmaceutical products face competition from a variety of sources. Depending on patent scope, substitute products within each therapeutic group may be widely available. Upon expiry of a patent, all firms are free to produce and market versions of the product. And because patents may not be sought or recognized in various markets, there are numerous imitative products available for nearly all therapeutic treatments, a situation that presumably will change considerably after TRIPS is fully implemented. The vast majority of pharmaceutical firms in the world produce generics, other substitutes under their own brand names, or imitative varieties of patented goods. Thus, beneath the top level of major pharmaceutical companies there are thousands of medicine producers in the world, making the industry highly competitive in most markets.

In the countries where basic and innovative research in pharmaceuticals is undertaken, the industry is the most research intensive of all sectors. Approximately 18% of pharmaceutical sales is spent on R&D by American drug companies (Congressional Budget Office, 1994). The after-tax R&D cost per new chemical entity (NTE) that is placed onto the market has been estimated recently at between \$194 million (\$359 million before tax credits) and \$241 million (U.S. Office of Technology Assessment, 1993; Di Masi, et al, 1991). The

Pharmaceutical Research and Manufacturer's Association currently estimates that it requires an average of \$500 million to discover and develop a new marketed medicine. Indeed, these costs per marketed product have risen considerably in real terms in the last decade. An important reason for these high R&D costs is that many failed compounds are investigated for each product that is shown to be safe, effective, and patentable. Another is that it takes a long time, on average 12-15 years in the United States, for a product to make it from basic pre-clinical research through clinical testing and regulatory marketing approval to product launch. This fact imposes a heavy capital cost in foregone interest on funds tied up in R&D. It is easy to see why appropriability problems are extreme in this sector in light of the high research costs and the low probability of product success. Imitative follower firms need only target those successful product launches with proven market demands, rather than undertake a comprehensive exploratory research program.

Distribution in the pharmaceutical sector is heavily regulated in most nations (Danzon, 1997). The purposes of such regulation are to control prices to consumers (hospitals and patients) and to limit budgetary costs of public health facilities. Prices may be directly regulated based on costs, wholesale and retail markups, inflation adjustments, and reference prices set through negotiations or by inspection of foreign prices. In some regulatory systems specific manufacturers and physicians are subject to revenue limits in an attempt to control prices or prescription practices. In others, firms are regulated by limits on returns to capital invested. Patient co-payments and managed care systems also effect limits on pharmaceutical prices and company revenues.

The effectiveness of various systems in controlling prices and procurement costs is debatable because of the many distortions these systems impose (Danzon, 1997). Among

OECD countries, pharmaceutical price indexes tend to be lower in countries with extensive price regulations, although these countries experience reduced availability of generics and over-the-counter drugs. However, real expenditures for drugs are not necessarily restricted by extensive regulation. In terms of impacts on innovation, it appears that innovative pharmaceutical research is encouraged in countries, such as the United States and the United Kingdom, in which firms are relatively free to set prices, while imitative research is encouraged in nations, such as France and Italy, in which price and revenue regulations are extensive.

It is not surprising that many developing countries, prior to TRIPS, failed to extend patent protection to pharmaceutical products, viewing the absence of patents as a form of limiting public health costs. Indeed, as noted earlier, in some industrial countries recognition of patents came only in recent decades. A number of developing nations have extended their patent laws to pharmaceutical compounds in recent years, but many do not yet recognize such protection. In part, this situation reflects the political power of local pharmaceutical firms that have developed behind weak patent systems, allowing them to produce and sell imitative products. Such firms will come under considerable competitive pressure as their governments enact patent protection for pharmaceutical products as required by the TRIPS agreement.

Biotechnology

The biotechnology industry remains dynamic, with the majority of firms being independently created to develop and sell a new genetic technological process or product. Thus, research in this field is performed largely by small firms, though the major

pharmaceutical, chemical, and agribusiness firms also undertake research, as do university scientists. Biotechnological inventions consist of genetic research tools, pharmaceutical products, transgenic strains of plants and animals, and biological industrial processes. It is estimated that roughly half the “important” drugs on the market and under development are based on biotechnological inventions (Rathmann, 1993). Research and development costs are also significant in this industry. Estimates of the costs of developing, testing, and launching a biotechnological medicine are comparable to those for pharmaceuticals more generally, while it is thought that costs for successful food products and genetic plant improvements are perhaps even higher (Rathmann, 1993). However, learning the biotechnological formula through reverse engineering is typically straightforward and inexpensive, generating again a considerable problem for original inventors in recuperating investment costs in the absence of protection.

Early forms of biotechnology products came from cloning proteins found in nature in order to develop commercially viable quantities. Because this research involves discovering genetic sequences rather than inventing them, there is considerable uncertainty about patentability of its outcomes (Barton, 1993). Moreover, knowledge of gene sequences (such as those being mapped in the Human Genome Project) is of potentially great value but the gene sequences themselves may not have industrial utility, rendering questionable the idea of patentability. Courts also find it difficult to identify a specific point of invention (isolation versus sequencing, which might be achieved by different claimants) for purposes of enforcing rights.

For these reasons and because of ethical and environmental concerns, a natural tension exists over the patentability of products involving living organisms. The United

States Supreme Court first addressed the issue in 1980 when it upheld the patent claim for an organism that would attack oil spills.²⁰ Although this organism was never commercialized, the recognition of organism patentability was a critical inducement to the U.S. biotechnology industry. Within two years, more than 100 companies were formed and today annual global sales exceed \$20 billion (Rathmann, 1993). Since that time, the American courts and the U.S. Patent and Trademark Office have moved sharply in the direction of strong and broad patent protection in biotechnology. Patents have been upheld covering all potential products from genetic engineering of a particular plant or a critical research tool, such as a genetic sequence developed for one drug but that could be required in developing numerous pharmaceutical products, all of which would be subject to the initial patent (Barton, 1995).²¹ Moreover, such patents encourage filing for protection over all potential genetic combinations, potentially limiting follow-on competition. Thus, critics characterize the American system as overprotective. Indeed, recent statements from the Clinton Administration encouraging the developers of maps of genetic sequences to make these maps of the human genome available widely to scientists, rather than to limit access through patents, points to rising concern about the effects of protection in core technologies.

The European Union generally has taken a more cautious view, though recently it has strengthened patent rights for microorganisms. Nonetheless, concerns over unknown health risks and the potential environmental impacts of engineered genetic materials merging with natural materials have caused numerous European nations to restrict their

²⁰ *Diamond v. Chakrabarty*, 444 U.S. 1028 (1980).

²¹ See U.S. Patent 5,195,135, 7 December 1994, Agracetus cotton patent covering genetic engineering of cotton plants and lines; and U.S. Patent 5,328,987, 12 July 1994, Maliszewski (Immunex) IgA FC receptors.

use in plants and animals for food supplies.²² Such concerns appear to be spreading to the United States and numerous farmers have chosen to forego further planting of genetically modified plants.

Many developing nations do not permit patenting of biotechnological inventions. This situation does not seem to reflect protection for local biotechnology firms, because few developing economies have successfully established a presence in the industry. Rather, it indicates concern over potential impacts of patents on costs of biologically activated pharmaceuticals, food products, and agricultural inputs, plus complex questions about regulating the exploitation of domestic genetic resources. Under terms of TRIPS, the obligation of countries to provide patents in biotechnology remains ambiguous, although the definition of excludable subject matter clearly is broader than that practiced in the United States (Maskus, 1998a; Watal, 2000).

Plant Varieties

The development of new plant varieties, which may be higher yielding or more disease-resistant than prevailing varieties, is accomplished by both biotechnological research and genetic mixing techniques. In the industrialized countries such research is performed in private chemical and agribusiness firms, university research laboratories, and public research institutes, including extension services. Such work in developing economies is largely undertaken by public universities and research institutes, which make seeds available to farmers at low cost. There are also publicly funded international research institutes that provide new strains to agricultural ministries for dissemination to

²² Pollin (1998) provides an entertaining and cogent summary of such concerns.

farmers. The best-known example is the International Rice Research Institute, which is commonly credited with developing higher-yielding and more robust rice strains that were widely planted in some developing countries.

As these comments suggest, agricultural research has long been considered something of a public good, because food supplies depend on research and widespread dissemination of new seeds. Limited intellectual property protection for new varieties reflected a policy tilt toward dissemination, requiring public research procurement. However, this view has changed fundamentally in recent years, with more countries recognizing advantages from shifting research into private facilities, supported by exclusive rights to research results. Indeed, under considerable pressure to reduce budgets or become self-financing, a number of public research institutes in developing countries have shifted sharply toward a more commercial orientation in order to remain competitive with a growing number of private breeders (UNCTAD, 1996). Limited evidence suggests that such institutes support IPRs in plant strains because they also wish to protect their own research results.

As in drugs and biotechnology, appropriability problems are significant in seed varieties. Plant varieties are protected by systems of plant breeders' rights, which combine patent-like protection with various limitations on the scope of rights. Thus, inventors are provided exclusive rights to produce, sell, and import seed varieties. The key exception to these rights is the farmer's privilege, under which farmers are allowed, after initial purchase of protected seeds, to retain for their own use sufficient quantities of seeds to plant the following year's crops. Another is the breeders' exemption, which allows competing breeders to use varieties freely in developing new strains. Such

exceptions to the exclusive use of seed varieties are not allowed under patent protection, as in the United States, so the choice between patents and this form of *sui generis* protection is important in determining the competitive nature of PBRs in each country.

The TRIPS Agreement obliges nations either to provide patents for new plant varieties or to provide less restrictive protection of the kind just discussed. The privatization of rights to the outcomes of agricultural research is among the most controversial areas of IPRs. Concerns arise on behalf of farmers in poor countries who might not be able to afford new agricultural inputs priced under IPRs protection, inducing them to use older technologies that would be less competitive in the marketplace. It is also argued that extensive recognition of PBRs could reduce genetic diversity over time, with unforeseen consequences for plant diseases and public health.

3.3b. The “Copyrights Complex” of Recorded Entertainment, Software, and Internet Transmissions

Copyrights protect original artistic and literary expression in numerous media, including print publishing, audio and video recording, live performances fixed in some medium, derivative products and services, broadcasts, software, video games, electronic databases, integrated networks, and electronic transmissions over the internet. Classical copyright doctrine envisioned only the first of these activities. Thus, it is not surprising that strains on the copyright system have emerged as its purview was extended to newer technologies and products. I illustrate these issues through a brief discussion of three critical areas that are at the forefront of the international policy debate in copyrights. Although recorded entertainment, software, and electronic commerce are commonly

considered distinctive economic sectors, they are closely interrelated through their extensive reliance on information technologies.

Recorded Entertainment

Among the more dynamic industries in the United States is film and music production. Global sales of these products have expanded dramatically in recent years, as has American employment in film and music production. The industry depends critically on advanced technology to achieve special effects and sound quality. It also invests considerable amounts in talent development and performers. Thus, there are substantial investment costs at the creative end. Moreover, product marketing is costly as firms attempt to establish quality reputations for differentiated acts and products. Thus, industry profits are protected both by copyrights and trademarks.

Unauthorized copying of recorded films and music lies at the center of international disputes over intellectual property rights. Incentives for pirating (copying and selling such goods without authorization) are easy to understand. It is cheap to acquire machinery for duplicating videotapes, digital video disks, and compact disks, but this machinery is capable of producing many copies with minimal diminution in quality. These copies are sold, with minimal distribution costs, at prices near marginal costs because pirating industries are generally fluid and competitive.

Piracy is the classical example of free riding in the copyright area. Pirating firms absorb no research costs and free ride on the creativity of performers and producers, allowing them to sell duplicates of original movies and records at a fraction of the price that would be supported by copyrights. The International Intellectual Property

Association annually estimates the revenue losses American firms suffer from limited copyright enforcement around the world. It claims that in 1995 such losses amounted to \$2.3 billion in motion pictures and \$1.3 billion in records and music. Estimated “piracy rates” ranged from 20% in Western Europe to 99% in Africa in films and from 5% in Western Europe to 70% in Eastern Europe in music.²³

The United States has expended considerable diplomatic energy convincing certain developing countries to enact and enforce copyright laws that would reduce piracy. Numerous countries have done so, both because of this external pressure and because emerging creative interests in those countries favor stronger copyrights. Moreover, anti-piracy efforts through adequate enforcement are required under terms of TRIPS. Accordingly, copyright protection in recorded entertainment should improve markedly, which is a signal victory for U.S. entertainment firms. However, effective enforcement of copyrights in developing economies will be delayed because of administrative costs and the existence of economic interests in pirating that will be difficult to overcome.

Computer Software

At the international level, software developers face problems similar to those in recorded entertainment, again because the high margins between protected software prices and costs of unauthorized duplication create large markets for pirated programs. The IIPA estimates that piracy losses to U.S. software firms in 1995 amounted to \$7.2 billion in business applications software (including platforms) and \$3.1 billion in computer games.

²³ These estimates are likely exaggerated because they assume that current sales levels would not fall in the

Piracy rates tend to be higher in business software than in any other form of recorded media. Illegitimate copies of programs such as Microsoft's Windows 98 and Office 97 are sold over the counter (with copies sometimes made while the customer waits) and loaded onto hardware systems. This activity constitutes literal copying of software code, meaning that copyright protection should be sufficient to reduce the problem. Hence, the global standard in software, as written into the TRIPS Agreement, is for countries to recognize computer programs as copyrightable expression. Again, this is a significant improvement from the standpoint of software developers, though adequate enforcement is years away.

While American software firms are pleased that there is a global commitment to accord copyright protection to their products, it is a minimum standard. In the United States considerably stronger protection exists through a combination of copyrights and patents, along with maintenance of trade secrets (Samuelson, 1993). The need for additional protection arises from the fact that literal application of traditional copyright precepts to computer programs may be too weak to provide incentives for innovation. Classical doctrine would make illegal only "slavish copying" of computer code, rendering it easy for competitors to develop rival programs by simply rewriting code in imitative ways. Thus, through judicial interpretation copyrights have been extended considerably to protect various aspects of programs. For example, the Third Circuit Court upheld the claim that the "structure, sequence, and organization" of programs are copyrightable, extending protection to interfaces and structural features of programs.²⁴ In another case the "look and feel" of programs through its computer interfaces was protected from being mimicked by

event of higher prices from eliminating piracy. See IIPA (1998a).

²⁴ *Whelan Associates, Inc. v. Jaslow Dental Laboratories, Inc.* 797 F. 2d 1222 (3d Circuit, 1986).

competitors.²⁵ Critics think such extensions do not fit comfortably with copyright doctrine, for they equate protectable expression with functional aspects of programs. This provides very long protection (copyrights last for author's life plus 50 years) to functional areas without corresponding novelty requirements, and may therefore be overprotective.

Similarly, American policy precludes reverse engineering of programs by allowing software firms to license their products subject to a no-decompilation clause. This structure is unusual in the copyrights area since other forms of expression, such as books and published music, may be studied by definition. Accordingly, computer programs prevented from decompilation bear no automatic disclosure. This policy is restrictive for decompilation is an important source of follow-on program innovation and permits interoperability of programs in an open environment. For this reason, the European Union follows a compromise solution by allowing decompilation to the extent needed to obtain information to create an interoperable program.

Computer programs and algorithms are also patentable in the United States and Japan, subject to novelty and utility demonstrations. Such patents recognize the functional aspects of software, such as programs that effectuate an industrial process. Software patents are criticized on two grounds. First, some critics complain that algorithms are discovered "truths of nature" and not patentable under classic doctrine. Second, patents provide strong rights to exclude others from using the idea underlying a particular functional program design, potentially according considerable market power to software firms that could be exercised in numerous using industries and through computer networks.

²⁵ *Lotus Development Corporation v. Paperback Software International*, 740 F. Supp. 37 (D. Mass. 1990).

This description points out that technology can render classical IPRs concepts difficult to sustain. The essence of the problem is that computer programs are “industrial literature” that embodies elements of both functional utility and literary expression. Some experts call for a hybrid form of protection that would combine shorter patent terms for functional aspects and copyrights for textual expression (Reichman, 1994). This view has not affected policy to date and the United States continues to provide full copyright and patent protection on various programs. It is not clear what the competitive implications of this system are but many observers, particularly within the software industry, consider it to be excessively protectionist.

Internet Transmissions

Electronic transmissions over the internet pose complex questions for copyright as well (World Trade Organization, 1998; Shapiro and Varian, 1999). Standard copyright principles apply to such transmissions under the TRIPS Agreement. Therefore, duplication rights and distribution rights are held by the copyright owner. However, enforcing these rights is difficult in digital products, which may be easily downloaded with no deterioration in quality. Indeed, users may compile their own music disks or videos without paying royalties to any of the original rights holders. Technology for such activity continues to improve, leading to calls for technical means to deter unauthorized downloading and distribution. The Copyright Treaty and the Performances and Phonograms Treaty (agreed at the World Intellectual Property Organization in December 1996) permit making illegal the use of technical means to circumvent electronic measures to control copying. They also facilitate collective management of copyrighted materials on the internet by permitting

identifying markers, the removal of which without authorization is illegal. They further clarify the rights of performers and music producers to authorize transmission of their works in the electronic environment.

The United States and the EU have adopted these treaties and amended their copyright laws in light of concerns by content providers that their materials were not well protected. For example, under the Digital Millennium Copyright Act, enacted into U.S. law in 1998, it is illegal to circumvent anti-piracy measures built into commercial software and to manufacture or distribute devices that defeat encryption codes, unless this act is done to conduct encryption research or to assess program interoperability. Limited exceptions for the anti-circumvention rules are provided nonprofit libraries and educational institutions. Internet service providers are excused from infringement liability for transmitting materials submitted by content providers, but are expected to remove evidently infringing material from users' websites. Fair use exceptions are provided to faculty members and students who wish to download a single copy of protected material for research or study, but these exceptions are subject to rigorous conditions. The law requires webcasters to pay licensing fees to record companies. Finally, it clarifies that it is illegal to distribute, in any form, electronically downloaded or uploaded materials without the authorization of the copyright holder.

Such laws, in effect, extend copyright protection to internet transmissions but extend copyright scope to regulations intended to defeat electronic piracy. Stronger copyrights should expand the supply of electronic materials available and contribute to the growth of electronic commerce. There should be significant additional gains associated with network

externalities, which bear the potential to markedly reduce transaction costs in international trade and to introduce new electronic products and services to wide areas of the globe.²⁶

However, the additional protection poses concerns for some users, such as university libraries and researchers, who worry about the effects on their access to, and ability to duplicate, research materials. Again, the issue is essentially the same as it is in the general arena of IPRs: stronger rights increase returns to creative activity but raise costs of enjoying that activity. Finding an appropriate balance between these two objectives is never easy.

This tension is illustrated well by the ongoing controversy over legislative attempts to extend copyright protection to databases. The European Union has done so through its Directive on the Legal Protection of Databases.²⁷ The United States has legislation pending in the form of the Collections of Information Antipiracy Act.²⁸ These acts strive to protect the investments of firms and researchers in the creative assembly of data compilations from the literal copying for commercial use by second comers, a laudable goal in principle. However, they go beyond measures that would establish such protection to conditions that could throw significant and costly barriers in the path of scientific researchers and educational institutions (Reichman and Samuelson 1997; Reichman and Franklin, 1999).

For example, as written these provisions would extend copyright protection to data compilations that require nothing more than arranging publicly available data into a particular order, thereby protecting materials that, under standard interpretation, should not be copyrightable. Researchers seeking to use scientific data so protected would be obligated to seek approval through a licensing arrangement, which could extensively raise research

²⁶ See Mann and Knight (1999) and Organization for Economic Cooperation and Development (1999) for discussions of the market-expansion impacts of electronic commerce.

²⁷ Directive 96/9/EC, March 1996.

²⁸ H.R. 354, 106th Congress; H.R. 2652, 105th Congress.

costs, particularly if the scientists needed to combine several databases from disparate sources. More chillingly, the owners of scientific databases could choose not to license them, tending to reduce the pace of technical change and scientific progress. Such licensing would be technically and legally feasible, given the legal ability of providers to attach binding licensing contracts (e.g., shrink-wrap licenses and standard-form contracts) to electronic data downloads. If a researcher attained a license, he could be prevented from sharing the data with other researchers, because exhaustion of rights at first sale does not extend to licensing contracts. Protection would last for 15 years but could be indefinitely extended if the database were improved. In principle, this provision would award to databases, a creation of limited inventive activity, protection that exceeds even the patent grant.

Under significant protest from the research communities, libraries, and universities, a number of proposed amendments to the U.S. legislation have been made. The objective is to extend standard concepts of fair use to database protection. Thus, researchers would be permitted to make and use single copies of data to the extent that their use and discoveries did not harm the commercial interests of the prior developer, a standard that is vague as currently written. Libraries would be allowed to make (at least) single copies for archival purposes and universities would have limited liability in the event the law was infringed by faculty and students.

The strongly protective EU directive and U.S. proposed legislation essentially reflect the accelerating view of data as a commodity. In part, this reflects the growing private use of data for purposes of marketing products and services. There is merit in providing copyright protection to expensively accumulated customer lists, for example. However, it also reflects

the blurring distinction between public research and its private uses. On current trends an increasing amount of research data will become private property, either because their generation was funded by private grants or because the researcher, working from public grants and data, sees commercial value in exploiting them.

3.3c. “Trademark Complex” of Status Goods and Quality Inputs

Trademark infringement is also common in many developing countries. Rising incomes in rapidly growing economies of Asia and Latin America account for a shift in demand toward such status goods as high-quality apparel, cosmetics, jewelry, and accessories. The substantial gap between market prices of legitimate products and costs of producing knockoff goods creates a thriving market for counterfeit merchandise sold without authorization under marks that are identical or confusingly similar to registered trademarks. It is again a classic free-rider problem. Creation of recognizable trademarks and reputations for quality requires significant investment in design, marketing, and quality control. Once this investment is made it is difficult to prevent expropriation or dilution of the trademark by second comers.

The problem plagues both well-known international brands and local enterprises that invest successfully in trademark development. Indeed, while stories of illegitimate use of foreign marks are well known, the unauthorized exploitation of local brand names may be even more prevalent, both because they may be more familiar to consumers and their owners may be less capable of enforcing their rights. In turn, inadequate enforcement of trademark regulations and unfair competition laws is a drag on business development and economic growth.

Trademark infringement occurs far more broadly than is often recognized. Beyond the obvious attempts to pass off counterfeit goods under names like Gucci, Chanel, and Rolex, marks and brand names are falsified in prepared foods and beverages, medicines, transport equipment, industrial machinery, electronic equipment, personal computers, and software, among other sectors. Thus, for example, unauthorized versions of Compaq computers and Microsoft programs have a market at least as much because of their reputations for quality as for their functional characteristics. Well-known manufacturers of industrial machinery, such as transformers, heating equipment, and construction cranes, also experience problems with local competitors selling like products with a false representation of trademark, licensing rights, or technology.

The ubiquitous and cross-sectoral nature of trademark infringement means that the firms harmed by it have widely varying interests in their operations in developing countries and are not easily organized into an effective lobbying campaign. In contrast, the concentrated patent (pharmaceuticals) and copyright (software and recorded entertainment) interests exert more influence on global policies through their national trade authorities (Ryan, 1998). Nonetheless, multinational firms are pursuing their rights more aggressively in key markets, such as China, while pushing for regulatory reform and additional enforcement. Moreover, the TRIPS Agreement calls for countries to recognize well-known trademarks, to remove onerous registration and use requirements, and to improve administrative and judicial enforcement .

Geographical Indications

A special category of protection exists for food products, wines, and spirits when the good bears a reputation for quality that is essentially attributable to its geographical origin. Without protection for indications of origin, competitors may pass off their products even if made in other locations. In turn, the value of investments in improving the original locations and marketing products is diminished. The TRIPS Agreement envisions two levels of protection. First, there is a requirement for countries to provide legal means to prevent false or misleading claims of geographical origin, applicable to any products. Second, there is special protection for wines and spirits that preclude the use of geographical terms with products that do not originate in the indicated area, even if accompanied by expressions such as “imitation” or “kind”. The Agreement further calls for negotiation of an international system of registration for wines and spirits in order to implement the higher level of protection.

The issue of protecting geographical indications has long concerned French vintners and Scottish whiskey distillers. The recent explosion in global demand for distinctive wines, spirits and food products lends further urgency to it, with high-quality winemakers in the United States, Australia, Chile, and elsewhere recognizing the potential value of such protection. At present the issue is largely contested among food and wine producers in developed countries and key developing countries such as Chile, Argentina, and South Africa. Many firms undertake global advertising campaigns based on the characteristics of production location. However, increasing numbers of firms in developing economies are exploiting the value of distinctive place names.

3.3d. Trade Secrets Issues

There is no identifiable “complex” of industries that rely on trade secrets for competitive advantage. The phrase “trade secrets” covers any form of industrial or commercial know-how that supports efficient production and that is maintained within the enterprise and its licensees as proprietary information. Such secrets could be chemical formulas underlying production of foods, medicines, and industrial chemicals, methods for heat transfer, construction techniques, bookkeeping or management systems, customer lists, and so on. Trade secrets are transferred internationally through FDI and technology licensing contracts.

Laws governing trade secrets define illegal attempts to learn and disclose proprietary information or to use it without authorization to develop competing production. Such laws vary widely across countries and even across states within the United States. The main source of contention, however, is inadequate laws and weak enforcement in developing economies. For example, allegations are made that public agencies, in reviewing proposed FDI or technology licensing agreements, leak confidential information to domestic competitors. It may be difficult to prosecute competitors that pay employees to divulge proprietary know-how. And there may be few restraints on the ability of managers and technical employees to leave the company and start a competing firm based on their acquired knowledge of trade secrets.

While TRIPS accords considerable discretion in the protection of undisclosed commercial information, it requires that countries develop systems for safeguarding such information from unfair competition, according to specified minimum definitions of illegal conduct. Further, undisclosed test data submitted for regulatory approval of agricultural chemicals and pharmaceutical products must be protected against unfair commercial use and

disclosure that is not necessary to protect the public. Legal and administrative enforcement of trade secrets must be improved as well.

3.4. Globalization and the Technology Content of Trade

The preceding discussion set out the essential tradeoffs and complexities in IPRs protection, including sectoral interests and international variations in protection. The existence of differential standards across countries is consequential because intellectual property accounts for a substantial and growing share of international trade and investment. Inventors and creators market their products and technologies globally, a fact that collides with weak and variable protection. Indeed, in recent years perhaps no other area of international commercial policy has come under greater pressure aimed at expanding the global reach of standards traditionally set in developed countries. This section provides evidence on the extent of international exchange of intellectual property.

3.4a. The Use of Intellectual Property Rights

It is difficult to devise accurate measures of the outputs of intellectual creation. Such outputs include both major inventions and minor product innovations, each of which may be patented but have vastly different economic and social values. They include slogans, logos, and brand names that may be trademarked but not necessarily put into use. Research activities may generate trade secrets, which by definition are not revealed in any published statistics. Finally, copyright registrations do not cover the vast amounts of creative materials for which registration is not sought, nor do they reflect the underlying value of particular

literary and artistic expressions. Thus, the contributions of intellectual work to economic activity, growth, and wealth creation are not easily measured.

Nonetheless, such contributions are important and growing in many countries, if judged by standard counts of intellectual property applications. For example, in Table 3.2 I list the number of patent applications in several countries or regions for the years 1990 and 1996. The 12 countries comprising the European Union (through the accession of Spain and Portugal) saw no increase in applications (row N) through their own patent offices, which handle perhaps 104,000 per year in total. The main reason for this is the diversion of applications to the European Patent Office (EPO), either directly or through the Patent Cooperation Treaty (PCT). These institutions allow centralized applications to be designated as valid in all EPO member nations in which protection is sought.²⁹ For example, the PCT permits an applicant to seek patent protection in multiple designated countries by filing an international patent application, thereby economizing on application fees.

It is evident that the EPO provides considerable economies to both resident and non-resident applicants. In 1996 there were 86,614 EPO applications, a rise of 88% over the 1990 level. These applications supported over 800,000 filings when extended to national coverage within the EU, suggesting that each EPO filing requested extension to nine countries on average. Non-residents are particularly likely to use the EPO to achieve coverage throughout the region.

In the United States, annual patent applications rose by 27% in the early 1990s, from 176,100 to 223,419. The mix between domestic and foreign applicants remained roughly

²⁹ The EU-12 countries comprise most of the countries in the EPO.

consistent, indicating a mature and open system. Non-resident applicants rapidly increased their filings through the PCT.

The rising numbers of patent applications in the EU and the United States in the 1990s are significant because they seem to reverse the widely discussed “patenting slowdown” in those countries in the 1970s and 1980s (Evenson, 1984; Segerstrom, 1998). American resident patent applications in the United States fell from approximately 72,000 in 1970 to a low of around 59,000 in 1983, and only returned to 1970 levels in 1988, with similar trends in Europe. These facts occasioned concerns about declining productivity of R&D programs, because over the same period real R&D spending and scientists and engineers employed in R&D rose sharply. It thus appears that these increasing investments are now resulting in growing patent applications, after some lag.

Table 3.2 about here

Japan has long had a system that encourages large numbers of applications filed to cover narrow claims (Ordovery, 1991). Moreover, specific features of the Japanese patent system, including utility models and pre-grant disclosure, favor frequent filings by domestic residents for small claims over infrequent filings by foreign residents over somewhat larger claims (Maskus and McDaniel, 1999). These characteristics are reflected in the patent data because 85% of all applications were filed by residents in 1996. This is a far higher percentage than exists anywhere else. However, the growth of foreign applications was larger than that for domestic applications, reflecting an expanding interest in protection in Japan. Overall applications rose by about six percent.

Canada and Australia represent developed economies in which non-resident applications are far larger than resident applications, though both types are rising rapidly. In both countries use of the PCT by foreign applicants rose dramatically over the period. Applications overall rose by 29% in Canada and by 59% in Australia.

The first four developing nations listed – Mexico, Brazil, China, and Korea – exhibited explosive growth in patent applications in the 1990s. Filings rose by a factor of five in Mexico and by 158% in Brazil. However, this growth was due entirely to non-resident applications, particularly through the auspices of the PCT. In contrast, Korea's near trebling of total applications featured a massive increase in domestic applications. China registered substantial increases in both resident and non-resident applications. Thus, both domestic residents and foreign firms are increasingly registering for protection in Korea and China, reflecting the importance of those markets, the ability of domestic enterprises to develop patentable technologies and products, and the improving climates for technology protection. The PCT is an attractive route to registration in both nations.

The Southeast Asian economies of Malaysia, Indonesia, and Thailand also saw total applications rise dramatically, dominated by increased foreign filings. Thus, these markets, characterized by high growth rates, successive rounds of economic liberalization, and some attempts to strengthen IPRs regimes, became more attractive locations in which to protect intellectual property in the 1990s.

Table 3.3 lists the number of applications for trademarks and service marks in the same years. In all countries the number of resident applications exceeds the number of non-resident applications. This is true especially in Brazil, China, Korea, and India, attesting to the fact that emerging economies tend to experience significant entry of new domestic

enterprises that find it advantageous to protect brand names for purposes of investing in product recognition. Except for Brazil, there was dramatic growth in annual trademark registrations over the period, with the number in China rising by 163%. The United States, Canada, Australia, and Mexico also registered significant expansion in trademark use. Within the European Union there was nearly a 10% rise in trademark filings, with non-residents making growing use of the registration procedures available under the Madrid Protocol (MP). Foreign enterprises also extensively employ the Madrid Protocol in China.

Table 3.3 about here

The figures in Table 3.4 are applications to register new plant varieties in various countries in 1992 and 1996. In the European Union, resident applications through national intellectual property offices, combined with applications through the Community Plant Variety Office (CPVO), rose from 2,812 to 3,225 over this period. Non-resident applications were heavily supplanted by applications through the CPVO. The United States saw a substantial increase in applications from both residents and non-residents, while non-residents chose to increase their protection for plant varieties rapidly in Japan. Both Canada and Australia experienced rapidly rising registrations from domestic firms. Argentina and Chile are listed as representative developing economies. It is only in South America that protective systems for plant varieties were commonly implemented in developing nations in this decade, though Brazil (among others) had not established such a system by 1996. Argentina saw a substantial rise in applications, dominated by non-resident filings, while applications in Chile fell off somewhat over the period. Korea established an application

system for plant varieties in 1992 and since then has registered a marked rise in non-resident applications. Thus, although this form of protection is relatively new in developing nations it appears that interest in its use is rising rapidly.

Table 3.4 about here

There are no centralized data for copyright registrations in different countries and, as indicated earlier, because in general copyrights need not be registered to be valid such data would reflect only a small part of the materials being created. One indirect way of representing the importance of copyrights is to consider data on demand for copyright protection implicit in publishing and viewing creative activity. Thus, Table 3.5 presents information on book titles produced, television receivers and personal computers per 1,000 members of the population, and internet hosts per 10,000 people in selected nations.

Annual figures on book production are subject to considerable cyclical pressures and must be treated with caution. Nonetheless, between 1991 and 1996 most countries reported notable increases in the output of titles, the exceptions being Canada, Brazil, and India. The EU members collectively published over 350,000 titles in 1996, with nearly a third of this sum accounted for by the United Kingdom, which is the world's largest publisher of books by title. The number of books published in the United States rose by 42% over the five years. China, Korea, and the Southeast Asian economies have become significant centers of publishing as well in the 1990s.

Televisions receive copyrighted programming and display copyrighted videos. The developed economies in Table 3.5 saw relatively small increases in the penetration of TV

receivers into households, reflecting near-saturation of that medium by the early 1990s. However, substantial increases were registered in Mexico, China, Korea, the Southeast Asian economies, and India. Clearly as incomes rise in such countries the demand for televised services and entertainment will continue to expand, suggesting a rising need for copyright protection.

Table 3.5 about here

Finally, the penetration of personal computers and internet services into households and businesses provides a measure of demand for computer software. While the figures in Table 3.5 are for a single year and therefore do not indicate growth rates, it is evident that software usage is growing rapidly in many countries (Mowery, 1996). Developing nations lag far behind in the spread of personal computers and internet connections, suggesting substantial room for growth as these economies expand.³⁰ In turn, copyright protection will prove vital for growth in use of legitimate software copies and for the international spread of internet commerce.

3.4b. International Trade in IPRs-Sensitive Goods

As I have noted elsewhere (Maskus, 1993) goods that rely extensively on IPRs protection tend to be among the fastest-growing items in international trade and also are distinctive in terms of international comparative advantage. This is unsurprising in light of

³⁰ The data on personal computers surely underestimates the number of PCs in place in developing economies because there is often a thriving underground business in the PC and software sectors (Maskus, 1997b).

underlying product characteristics, including advanced technological content, rapidly evolving dynamics in technology, and marked quality differentiation.

Strong indication of these facts is provided in Table 3.6, which shows trade growth and a simple measure of revealed comparative advantage (RCA) for a selection of product categories in 1990 and 1996. The first set of columns lists nominal gross trade (exports plus imports) in billions of U.S. dollars for total merchandise and percentage growth in nominal trade. Clearly, this growth rate depends not only on volume increases but also on inflation and exchange rate variations. However, my interest here is in demonstrating the relatively rapid expansion of sectoral trade. Thus, a comparison of trade growth by sector with aggregate trade growth should be largely free of inflation and exchange rate effects. Finally, for each commodity group I list an RCA index, which is the ratio of group exports to group imports, divided by the ratio of total merchandise exports to total merchandise imports. Thus, RCA measures the extent to which the sectoral trade pattern differs from each country's overall trade pattern. An index well in excess of unity suggests an underlying comparative advantage while an index below unity suggests a comparative disadvantage.³¹

Table 3.6 about here

The product groups chosen cover sectors that feature prominently in international debates over IPRs, including patents in pharmaceuticals, chemicals, machinery, and instruments; chip topography protection in microcircuits; trademarks in alcoholic beverages

³¹ RCA indexes should be treated with caution, as they depend also on sectoral trade protection, subsidies, and other factors. However, ratios quite different from unity are surely meaningful, as are comparisons over time within a country. Moreover, because these indexes are computed solely on trade flows they do not reflect production advantages associated with FDI for local markets.

and perfume and cosmetics; and copyrights in printed matter and sound recordings. Clearly these sectors do not exhaust all categories in which IPRs loom large. Moreover, they are broad aggregates covering a large mix of products of varying ages and technological contents, so they do not necessarily correspond closely to product-specific demands for IPRs. Nonetheless, they seem to tell a consistent story.

As might be expected, aggregate merchandise trade rose most rapidly in the 1990s for the developing economies in the sample, especially Korea, China, and the Southeast Asian economies (MIT). Among the developed economies, American trade rose most rapidly in nominal terms. Overall the EU12 nations saw a 34% rise in merchandise trade. This aggregation of European economies clearly masks considerable national variation in trade performance, a fact that carries over into, and clouds, the sectoral analysis.

There is much to digest in Table 3.6 and I simply highlight interesting cases. The pharmaceuticals and medicines group (SITC 541) saw relatively rapid trade growth in all countries except China, MIT, and India. The United States maintained a substantial, though declining, RCA in pharmaceuticals as its gross trade more than doubled. Japan demonstrated a comparative disadvantage in the sector, in considerable contrast to the other high-technology industries in the table. China's RCA indexes were well above unity, mainly reflecting a near-absence of imports in drugs and medicines but a substantial export trade. These ratios are likely to moderate as China improves its patent protection for imported drugs and liberalizes import restrictions. India saw a marked deterioration in its RCA for pharmaceuticals in the 1990s. India's export strength in this sector has been based on competitive imitation and production of products that were not patentable in India and its

export markets (Watal, 1996; Marino, 1998). Recently the country has seen rapid growth in imports of medicines and it is again a net importer.

Nearly all countries experienced relatively fast trade growth in special industry machinery (SITC 728), machine tools (SITC 73), electro-medical machinery (SITC 774), and measuring and controlling instruments (SITC 874), and computers (SITC 752).³² Save the last category, these high-technology machinery sectors are areas of revealed comparative advantage for the United States, the European Union, and Japan and are also areas in which patents are commonly registered. Thus, these countries clearly are net exporters of technology embodied in such machinery, which helps explain their keen interest in stronger global patent rights. At the same time, these machinery categories revealed significant comparative disadvantages in nearly all other countries, especially developing countries. Mexico and Korea are noteworthy in registering marked increases in their RCA indexes in high-technology machinery, providing a crude explanation for their rising interests in implementing stronger patents during this period. Canada and Australia remain net importers of these machinery categories.³³

Perfume and cosmetics (SITC 553) are representative of highly differentiated consumer goods that are sold under familiar trademarks and that are subject to considerable infringement. Trade growth has been especially rapid in this group except in China and India, which sustain unusually low import levels, accounting for their high RCA indexes. Mexico, Brazil, and Korea are rapidly expanding markets for such goods. Again, these are decided net-export commodities for the European Union and the United States, consistent

³² The EU12 is a frequent exception, reflecting cross-currents in trade data that emerge through the aggregation of disparate countries.

³³ Again, these categories are aggregates of detailed machinery sub-groups. At more disaggregated levels Canada and Australia would undoubtedly register RCA indexes above one in many sub-groups.

with their strong advocacy of cracking down on trademark piracy. Trade growth has been less rapid in alcoholic beverages (SITC 112), an area of strong comparative advantage for the EU, Australia, and Mexico. As noted earlier, the EU has been the strongest advocate of a global system of registration and protection for geographical indications in wines and spirits.

Finally, trade growth in printed matter and sound recordings has been especially great in the developing economies. The United States, Japan, and the European Union (especially the United Kingdom) retain net-export positions in publishing at this aggregate level.³⁴ Canada and Australia are significant net importers of published materials, a fact that helps explain Canada's support for its cultural industries and Australia's recent decisions to permit parallel importation of books and music compact disks. In any event, these figures suggest that effective copyright protection in developing countries is of rising interest to publishers in the developed world.

3.4c. Licensing and Foreign Direct Investment

Table 3.7 provides perspective on trends in trade of services that are sensitive to IPRs protection. Indicators include net trade in computer and information services (IT) and royalties and license fees (RLF), both as reported in the IMF's *Balance of Payments Statistics*. The latter variable is what the OECD refers to as the "technology balance of payments." It comprises "...money paid or received for the use of patents, licenses, trademarks, designs, inventions, know-how, and closely related technical services" (OECD, 1998). Not all countries report each of these flows so there are some gaps in the coverage. All data are reported in U.S. dollars at prevailing exchange rates. Accordingly, the 1996

³⁴ Unfortunately, software is not a category broken out separately in the international trade data.

figures are deflated by the U.S. wholesale price index to achieve a crude measure of changes in trade volumes.

There are several reasons why published data on RLF may not capture adequately the amount of technology being traded. Licensing fees are determined through complex contracting procedures, which attempt to price the implicit value of information. Information is unlike standard commodities in that its ultimate economic value may be unknown at the time a contract is struck. Further, the fees paid may be influenced by tax provisions, accounting rules, and management decisions regarding the extent and form of income repatriation. Finally, joint ventures, business alliances, and cross-licensing agreements may encompass different volumes of licensing than would be suggested by straightforward licensing fees. Thus, such figures should be treated with caution.

Table 3.7 about here

Data on credits and debits for the EU countries are sums of gross flows and therefore do not net out intra-EU trade. However, in principle two-way flows within the EU should cancel in computing trade balances, which therefore do indicate extra-EU net trade. With this caveat, note that gross receipts of and payments for computer and information services amounted to around \$6.6 billion in 1996, a substantial rise from 1990 levels. Both receipts of and payments for royalties and license fees rose by over 50% within the European Union over this period, indicating a substantial increase in international licensing of technologies and trademarks. On net the EU-12 nations remain net payers of RLF, reflecting the

existence of substantial net importers of intellectual property (including France, Germany, Ireland, and Spain) within that region.

The United States also experienced significant increases in receipts of and payments for RLF, with payments more than doubling. However, the near-doubling of RLF earnings from abroad generated a large rise in net receipts for intellectual property. Indeed, the United States remains by far the largest global net supplier of technology, trade secrets, and IPRs for which royalties are paid. For its part, Japan is a net importer of both computer services and intellectual property and has also seen a marked rise in transactions requiring license fees.

That rapid growth is associated with rising technology imports seems clear from looking at the remarkable increases in the volume of RLF payments by Brazil, the Southeast Asian economies and especially Korea from 1990 to 1996. Korea's outward payments rose fifteen-fold in this six-year period, resulting in net outward payments for RLF of over two billion dollars by the later year. In contrast, India's gross RLF payments grew marginally while Mexico's payments actually fell, which was likely a result of the macroeconomic crisis in the middle of the decade.

A final means of trading intellectual property is by transferring information to subsidiaries through foreign direct investment. Table 3.8 presents basic indicators on trends in the stocks of inward and outward FDI between 1990 and 1996. That FDI has risen more rapidly than output in most areas of the world in recent years is clear from the figures on investment stocks as a percentage of GDP. With few exceptions these ratios rose sharply during the early 1990s. The European Union, the United States, and Japan remained large net suppliers of FDI, while Canada and Australia had larger inward stocks. The rise in

inward stocks was especially large in Mexico, Brazil, and China, while Korea has become a significant investor in its own right. To the extent that such investments embody intellectual property, these figures suggest that FDI has become also an important source for trading and exploiting IPRs internationally. These are issues to which I devote considerable attention in the following chapters.

Table 3.8 about here

3.5. Pressures for Change in the Global IPRs System

The figures just reviewed suggest two broad conclusions. First, the 1990s have been a period of rapidly expanding international economic activity, particularly as regards implicit or explicit trade in technology and goods protected by intellectual property rights. Second, resort to IPRs through patent applications and trademark registrations is rising rapidly, particularly in major developing economies.

That the international demand for IPRs is rising stems largely from the fact that in a globalizing economy the creation of knowledge and its adaptation to product designs and production techniques are increasingly essential for commercial success. In this environment firms wish to exploit their technical advantages on an international scale and also to limit expropriation costs from potential rivals. These tasks are made easier by the adoption of stronger and more uniform IPRs in different countries. Thus, globalization of technology trade is itself the key factor in explaining systemic change in intellectual property rights.

Two other factors are critical as well. One is that the costs of copying and imitating products from important sectors of technology are falling, making infringement easier and more prevalent. This is evident in the case of electronic media, such as software, computer games, compact disks, and videos, which may be reproduced cheaply and in bulk with little or no quality degradation. Similar problems plague unauthorized duplication of broadcasts and internet products and services, a fact that has materially retarded the international provision of electronic information. In pharmaceuticals, the costs of original product research and marketing continue to grow rapidly, but imitation costs remain low. Many biotechnological products, in particular, are subject to considerable investment costs but may be copied at a small fraction of original expense. It is also straightforward to duplicate industrial designs, such as tile patterns or machine configuration. In all of these cases, copying costs are falling relative to original development costs, in large part because of efficiencies from applying computer technologies to imitation tasks.

A final strain on the classical IPRs system, as discussed earlier, is that many of these newer technologies do not fit comfortably within standard conceptions of industrial property and artistic property. Computer microcircuits, software programs, biotechnological inventions, and electronic transmissions all strain the limits of classical patent or copyright laws. Thus, even within developed countries the area of intellectual property law remains in considerable flux.

These elements explain the substantial rise in demand on the part of intellectual-property owners for stronger and more harmonized global standards of protection. In turn, they underlie the massive efforts mounted by authorities in the United States and the European Union to reform the global IPRs system. These efforts have been ubiquitous,

incorporating numerous bilateral negotiations with particular developing nations under threat of trade sanctions, comprehensive regional trade agreements that include IPRs chapters, the multilateral TRIPS Agreement and its prospective review in the year 2000, ongoing efforts to unify legal practices within the EU, and international negotiations under the auspices of WIPO over intricate aspects of copyright for electronic transmissions.

3.6. Summary

Intellectual property rights are complex phenomena that cannot readily be captured by the phrase itself. They exist in a variety of forms, including patents, copyrights, trademarks, trade secrets, and mixed forms of protection, that operate in distinctive fashion. They are aimed at achieving somewhat different goals, which vary by subject matter and economic sector. Ultimately, however, IPRs attempt to strike an appropriate balance between providing adequate incentives to develop new technologies, products, and artistic creation, on the one hand, and ensuring effective distribution of those inventions into the economy. As policy tools, IPRs are second-best solutions to the difficult and delicate mix of failures that arise in markets for developing and selling information. Nonetheless, because they are market-based incentives they are generally much more efficient than direct public provision of invention.

While all industries make use of a portfolio of IPRs, it is useful to identify specific sectors with the need for particular types of intellectual property protection, for these sectors dominate the global policy debate. Patents are especially critical in the pharmaceutical and biotechnology industries, while plant breeders' rights add a complementary form of protection. Each of these areas raises contentious issues about the economic and social

implications of protecting exclusive rights to new knowledge. Even within the United States, the bastion of strong protection for intellectual property, debate persists about the wisdom of awarding broadly specified patents to biotechnological tools, genetic sequencing, and life forms. This approach is unlikely to be widely adopted in developing countries for the intermediate future.

The copyright-dependent sectors include software, recorded entertainment, electronic broadcasts, databases, and internet commerce. Computer software falls uncomfortably between copyright and patent principles and is subject to varying treatment in different countries. Copyright procedures, in principle, seem adequate for the protection of internet transactions but may require supplementation with technical solutions to endemic problems of appropriability. The protection of databases remains controversial for it could reward activity with limited creativity and yet pose potentially significant difficulties for scientific and educational uses of information.

The use of trademarks is widespread in all forms of business and generally poses little threat to competition while providing important incentives for product development and quality improvements, thereby benefiting consumers and reducing their search costs. Trade secrets permit firms to protect proprietary information that they do not wish to patent. Often such information is in the nature of small and incremental, sub-patentable inventions. Trade secrets protection can promote the development of such inventions and also encourage their diffusion into competition via reverse engineering.

Given these potential impacts of IPRs and the growing need, stemming from globalization of technology, to exploit new information in international markets, the registration and use of intellectual property is expanding rapidly. Patent and trademark

statistics point to the rising recourse to protection in virtually all countries. Figures on trade, FDI, and licensing receipts suggest further that the relative IPRs-intensity of international economic activity is growing over time.

Nonetheless, these increases are not shared equally across nations. Patent applications on the part of firms from developed economies continue to dominate global registrations. It remains true that developing countries are overwhelmingly net importers of technology and new products. Thus, an inherent tension exists among countries at different levels of economic development in their perceived interests in the global and national systems of protection. This theme is developed at length in the following chapter.

Notes: EU12 designates the first 12 members of the European Union; MIT is the sum of Malaysia, Indonesia, and Thailand. IT designates computer and information services; RLF designates royalties and license fees; ^amillions of dollars; ^b1991; ^c1995; ^ddata for technology balance of payments. Data for 1996 are deflated by U.S. wholesale price index (1990 = 100). Sources: International Monetary Fund, *Balance of Payments Statistics Yearbook 1997* and *International Financial Statistics*, various issues, and Organization for Economic Cooperation and Development, *Basic Science and Technology Statistics 1997*.

Table 3.8. Inward and Outward Stocks of Foreign Direct Investment

Country	1990				1996			
	Inward (\$b)	%GDP	Outward (\$b)	%GDP	Inward (\$b)	%GDP	Outward (\$b)	%GDP
EU12	691	10.9	724	12.0	1026	13.0	1309	16.8
USA	395	6.9	435	7.6	630	8.3	793	10.4
Japan	10	0.3	201	6.8	30	0.7	259	5.6
